

AWS VPC Configuration Assignment

InstaVibeVPC – Public and Private Subnet Setup

1. Create the VPC

VPC Name: InstaVibeVPC

IPv4 CIDR: 10.0.0.0/16

Open the AWS VPC Dashboard → Your VPCs → Create VPC. Select an IPv4 CIDR block and enter 10.0.0.0/16.

2. Create Two Subnets

Subnet Name	Type	IPv4 CIDR	Purpose
PublicSubnet-Zomato	Public	10.0.1.0/24	Web server / public users
PrivateSubnet-Zomato	Private	10.0.2.0/24	Backend services / database

3. Configure Internet Gateway

Create an Internet Gateway named **InstaVibe-IGW** and attach it to **InstaVibeVPC**. The Internet Gateway itself is attached to the VPC; internet access is controlled through route tables. Therefore, only the public subnet receives a route to the Internet Gateway.

4. Configure Route Tables

Public Route Table: Associate it with PublicSubnet-Zomato and add route **0.0.0.0/0** → **InstaVibe-IGW**. This allows internet-bound traffic from the public subnet, assuming the resources also have the required public IP/security configuration.

Private Route Table: Associate it with PrivateSubnet-Zomato and do **not** add a route to the Internet Gateway. Thus, the private subnet has no direct internet route.

5. VPC Diagram

6. Similarity to Apps Like Zomato

A food-delivery application can separate its public-facing web/application components from sensitive backend systems. The public subnet can host components that need internet access, while backend services and databases can remain in a private subnet. This reduces direct internet exposure of sensitive resources. In AWS, route tables help control which subnet has a direct route to the Internet Gateway.

Verification Checklist

- ✓ VPC created: InstaVibeVPC – 10.0.0.0/16
- ✓ PublicSubnet-Zomato – 10.0.1.0/24
- ✓ PrivateSubnet-Zomato – 10.0.2.0/24
- ✓ Internet Gateway attached to the VPC
- ✓ Public route table has 0.0.0.0/0 → Internet Gateway
- ✓ Private route table has no Internet Gateway route
